Introduction

A synthetically generated warning picture...

- “A developer upgraded to Ubuntu 22, which broke his computer setup, one week before an important presentation” [DALL-E 2]

Image © [Haoran Li](#), [Li Xiong](#), [Lifan Zhang](#), and [Xiaoqian Jiang](#),

“DPSynthesizer: Differentially Private Data Synthesizer for Privacy Preserving Data Sharing”

- Create a **fictitious dataset** that **mimics** an actual dataset by **learning** its structure and **generating** plausible datapoints

Why?

- Access to data is not always as simple as “sign this NDA and it’s fine”

Source: "Towards the European Health Data Space", Markus Kalliola, TEHDAS

- Regulatory requirements for re-use of sensitive data, not limited to:
 - “Sufficient / adequate” technical and organizational measures
 - Explicit permission from data subjects
 - Anonymization / aggregation
 - Obligations to delete data
 - Writing impact assessments, keeping registries, ...
 - Real data can be
 - Expensive to collect
 - Unbalanced
 - Incomplete
- Synthetic data can avoid more than one headache

- Focus on statistical modeling for **tabular data** in textual form
- Dive into the **practicalities** with an **open-source** approach in Python
(yeah I know)
- Usecases
 - Making a **realistic alternative to (sensitive) data** available, e.g.
 - As a data controller, to universities for research
 - As a university researcher, to the outside world for reproducibility
 - As a company, to the architects, developers and testers that build your software
 - Data augmentation for ML applications
 - Realistic simulations / generate test data
 - ...

Approaches

- Lorem ipsum ...
- Predefined structure/schema in which the gaps need to be filled
 - Random number/text generators
 - Lists of names, addresses, cities, locales...
 - Shuffling existing data
 - Inverse of regex matching
 - ...
- Libraries that do this will offer several generators for common data types, formats and locales

- Faker [<https://faker.readthedocs.io/>]
 - Also for PHP, Perl, Ruby, Java, ...
- Mimesis [<https://mimesis.name/>]

```
from mimesis import Generic
from mimesis.locales import Locale
g = Generic(locale=Locale.ES)

g.datetime.month()
# Output: 'Agosto'

g.code.imei()
# Output: '353918052107063'

g.food.fruit()
# Output: 'Limón'
```

- Extensible with custom generation routines and schemas for your own datatypes

```
from faker import Faker
fake = Faker('it_IT')
for _ in range(10):
    print(fake.name())

# 'Elda Palumbo'
# 'Pacifico Giordano'
# 'Sig. Avide Guerra'
# 'Yago Amato'
# 'Eustachio Messina'
# 'Dott. Violante Lombardo'
# 'Sig. Alighieri Monti'
# 'Costanzo Costa'
# 'Nazzareno Barbieri'
# 'Max Coppola'
```

```
>>> Faker.seed(0)
>>> for _ in range(5):
...     fake.vat_id()
...
'BE6048764759'
'BE8242194892'
'BE1157815659'
'BE8778408016'
'BE9753513933'
```

2. Statistical modeling

- Similar “summary statistics” $\neq$ good mimicking of original data

- Conservation of distributions $\neq$ conservation of correlations

Age	Retired
15	FALSE
24	FALSE
50	FALSE
68	TRUE
72	TRUE
88	TRUE

Age	Retired
88	FALSE
68	TRUE
50	FALSE
15	TRUE
72	FALSE
24	TRUE

2. Statistical modeling

- 1. Learn (joint) distributions from original data → model
- 2. Repeatedly “sample” this model

Image © [Haoran Li](#), [Li Xiong](#), [Lifan Zhang](#), and [Xiaoqian Jiang](#),
“DPSynthesizer: Differentially Private Data Synthesizer for Privacy Preserving Data Sharing”

- Conditional sampling: keep some values fixed to sample a subset

3. Simulation of the generative process

- Generate data for rare or expensive events
- Create annotated datasets for machine learning

- **Agent-based Modeling**
 - Complex dynamic systems (e.g. physics/biology simulations)
 - Generate interaction data
 - Tools: specialized frameworks: Repast (C++), MASON (Java), Mesa (Python), ...
- **Virtual Environments**
 - Robotics, self-driving, VR
 - Generate large amounts of different scenarios
 - Tools: 3D engines: Unity3D, GTA, X-Plane, ...
- **Synthesizers**
 - Audio, speech, generative artwork
 - Generate multimedia from (textual) annotations
 - Tools: text-to-speech systems, MIDI, WaveNet, Processing, ...

In practice

- Let's take a dataset and pick a software library:

	age	workclass	fnlwgt	education	marital-status	occupation	relationship	race	sex	hours-per-week	native-country	capital	income
0	39	State-gov	77516	Bachelors	Never-married	Adm-clerical	Not-in-family	White	Male	40	United-States	2174	<=50K
1	50	Self-emp-not-inc	83311	Bachelors	Married-civ-spouse	Exec-managerial	Husband	White	Male	13	United-States	0	<=50K
2	38	Private	215646	HS-grad	Divorced	Handlers-cleaners	Not-in-family	White	Male	40	United-States	0	<=50K
3	53	Private	234721	11th	Married-civ-spouse	Handlers-cleaners	Husband	Black	Male	40	United-States	0	<=50K
4	28	Private	338409	Bachelors	Married-civ-spouse	Prof-specialty	Wife	Black	Female	40	Cuba	0	<=50K

[Source: Kaggle, "Adult Census Income" dataset: <https://www.kaggle.com/datasets/uciml/adult-census-income>]

- <https://sdv.dev/>
- One of the larger open source Synthetic Data libraries (in Python)
- Supported methods:
 - Statistical: “copula” multivariate distributions
 - Deep learning: CTGAN (GAN for tabular data) / TVAE (Tabular Var. AutoEncoder)
 - Time series (in development) : PAR (Probabilistic AutoRegression)
 - Relational data (linked tables) : hierarchical model with underlying copula models
- Encode your own constraints
- Some evaluation and benchmarking options (limited)
- Commercial support by Datacebo Inc.

```
from sdv import load_demo, SDV

# Use pre-loaded demo tables
metadata, tables = load_demo(metadata=True)

sdv = SDV()
sdv.fit(metadata, tables)

synthetic_data = sdv.sample()
print(synthetic_data)
```

```
1 # Display basic statistics about the dataset
2 print("Data description - categoricals:")
3 actual_data.describe(include='object', datetime_is_numeric=True) |
```

Data description - categoricals:

	workclass	education	marital-status	occupation	relationship	race	sex	native-country	income
count	48842	48842	48842	48842	48842	48842	48842	48842	48842
unique	7	16	7	15	6	5	2	42	2

freq	14538	15604	19432	6293	15757	26779	27479	7253	31275

... or in graphical form ...

- SDV's default built-in models deal **particularly badly** with:
 - Highly **skewed** or **irregular** distributions
 - Distributions with **long tails**
 - **Rare or unique values** (tend to be ignored)

→ but this is all very common in real life datasets!
- There is a **structural limit**:
for rare values, there are not enough datapoints to be able to learn conditional distributions, nor correlations with other variables
- Tweaking SDV's parameters can help but doesn't do miracles

Adding CTGAN to the mix

Copula (stat.)

Copula+CTGAN

What happens with numbers?

What happens with numbers?

```
1 actual_data['capital'].nunique()
```

221

```
1 new_data['capital'].nunique()
```

17428

- SDV does not know the **meaning** of any number
- Assumes **smooth** distributions -> **interpolates** when sampling
- In this dataset
 - “hours-per-week” behaves more like a categorical variable (fulltime, parttime, ...)
 - “capital” has plenty of 0, which might mean “no info / null” instead of “capital = \$0”

It's not as easy as
“Load data & press start” ...

- What does a missing data point mean?
 - Numericals: can appear as NaN, but sometimes also 0, -1, -2^{32} , ...
 - A missing year of birth doesn't mean a person was born in the year 0
 - Booleans: missing data = FALSE or missing data = third category?
- SDV deals in a peculiar way with missing data:
 - Categorical variable: considered just another category within the variable
 - Numerical variables are split in 2
 - 1 Boolean variable to decide "is it null"?
 - 1 numerical variable trained on all non-null values
 - Boolean variable: null values not supported
- Not possible (yet) to generate data conditional on the absence of other data.

- Suppose our dataset masked the ages of all people <21 by setting it to -1

- Suppose that 'capital==0' actually means: no data (NaN)

- Some datasets contain **count data**:

Frost	Rain	Sun	# days
No	No	Yes	52
No	Yes	No	43
Yes	No	Yes	1
No	No	No	187
No	Yes	Yes	10

(obviously this table does not say that frost is present in 20% of the datapoints)

- For a correct data model:
 - 1. “unroll” the data (= undo the counting, expand) and delete count variable
 - 2. train the model and generate synthetic data
 - 3. recount / regroup the synthetic data

- There are no guarantees that a particular value will be drawn from the distribution, especially when those values are rare:

	race	sex	native-country
count	48842	48842	48842
unique	5	2	42
top	White	Male	United-States
freq	41762	32650	43832

	race	sex	native-country
count	48842	48842	48842
unique	4	2	24
top	White	Male	Cuba
freq	26779	27479	7253

- Conditional generation** allows to force the desired quantity of a value
- Conditioning on rare values may give repetitive results (because not enough data to properly learn conditional distributions)

- Columns can be fully dependent on others:

X	Y	X+Y	2Y-X
2	4	6	6
8	7	15	6
0	1	1	2
1	0	1	-1

- SDV cannot detect dependencies, only approximately learns correlations
- For a correct data model:
 - Remove dependent columns
 - Learn model and generate data
 - Re-calculate and re-add the dependent columns

- The **meaning** of the data may imply other dependencies
 - Date of birth < date of death
 - City = Antwerp → Province = Antwerp → postcode.startsWith('2')
 - Age < 18 → child_benefits = true
 - Distance > 0
 - \$ORCL = Oracle
 - A 25-year-old in year X, cannot be 36 in year X+1
- Encode these in **constraints**
 - Some can be incorporated in the model
 - Others can be enforced by **fusing columns**
 - Others can be enforced through **rejection sampling**

Wrapping up

- Synthetic data tools **rarely work out of the box** for datasets “in the wild”
 - Your model likely needs **finetuning** -> iterative process
 - You’ll often want to add **custom preprocessing** for your data
- Long-tailed or irregular distributions complicate things and can give rise to **statistical instability**
 - Various strategies can mitigate the worst side-effects, but there is no silver bullet
- **Know your data**

- Minimize the number of columns
 - To anonymize a dataset with *address* and *gender* : only synthesize new addresses
 - Discard columns that don't need to be resynthesized
- Exploit knowledge about the data
 - Fuse columns that are strongly correlated (e.g. city and its province)
 - Use constraints to prevent generating nonsensical datapoints
 - Decide what to do with outliers and missing data and why
 - Merging the least-used categories into an “other” category, reduces the “long tail”
- Work with a well-selected sub-dataset to speed up finetuning

- Possibilities for analytics on synthetic data are **limited!**
 - Structure of the data is **approximately** mimicked
 - **1** variable statistics (min, max, avg, etc) are **mostly** preserved,
 - Links between **2** variables (correlation, ...) are **somewhat** preserved,
 - Links between **more** variables (regressions, ...) are **poorly or not** preserved,
- The suitability of synthetic data as **drop-in-replacement** for real data depends on usecase and data properties...
- We obtained the best results on datasets with
 - Few variables (columns)
 - Many datapoints for each value of each variable

- Modify personal data such that the original can no longer be derived
 - Related concepts: *differential privacy, k-anonymity*
- Privacy is improved by
 - Removing identifying attributes
 - Generalizing (e.g. only keep the year from a birthdate)
 - inevitable *loss of information* and/or utility (which synthetic data tries to mitigate)
- On the model side: prevent overfitting / memorization of training data
- Toolkit for evaluation: ARX

- SDMetrics library (under development) provides some toolkit-agnostic evaluation routines
- Commercial providers often provide well-illustrated analysis reports
- e.g. these cross-correlation graphs from gretel.ai :

the market

- Commercial market for synthetic data tools is booming

TONIC

THE FAKE DATA COMPANY

gretel

BENERATOR

THE SMART WAY
TO HANDLE DATA

Configuration: example tonic.ai

The screenshot shows the Tonic.ai web application interface. The browser tab is titled 'Tonic' and the address bar shows 'app.tonic.ai/bulk'. The workspace is set to 'Privacy Scan Demo'. The sidebar on the left contains the following navigation items: TONIC, Privacy Hub, Database View (highlighted with a red arrow), Table View, Jobs, Autodetect, Schema Changes, Subsetting, and Collapse. The main content area is divided into two sections. The left section, titled 'Tables', shows a list of tables under the 'public' schema: customers (5), customers_legacy (6), date, employees (5), marketing (5), products, retail_sales, stores (1), vendors (1), wholesale_orders, and wo_date. Each table has a menu icon (M) and a link icon. The right section, titled 'Every table', shows configuration options for filters. It includes two filter groups: 'All Private Not Private' and 'All Protected Not Protected'. Below these is a 'Column search' input field. The list of columns and their configurations is as follows:

Column	Filter	Type
customers.Customer_Key	Key	
customers.First_Name	Name	First
customers.Last_Name	Name	Last
customers.Gender	Categorical	
customers.Email	Email	Domain : Random
customers.Marital_Status	Passthrough	
customers.Number_Of_Children	Passthrough	

Red arrows point to the 'Database View' in the sidebar, the 'Column search' input field, and the 'Passthrough' filter for 'customers.Marital_Status'. A 'Clear selection' button is located at the bottom of the table list.

JRC TECHNICAL REPORT

Multipurpose synthetic
population
for policy applications

Hradec, J., Craglia, M., Di Leo, M., De
Nigris, S., Ostlaender, N., Nicholson, N.

[DOI 10.2760/50072 – July 2022]

“Current methods of data synthesis using open source tools are relatively powerful but only for flat tables, with limited number of constraints, low cardinality categorical variables and continuous, without hard breaks.”

“Commercial solutions still beat the available research and open source solutions by a huge margin at the time of writing.”

“The field is evolving very fast and we may expect competitive open source solutions in the near future.”

And now what?

- Synthetic data, when quality-checked and carefully crafted, is **free of privacy and other regulatory issues**.
- The elimination of bureaucracy associated with sensitive data access, enables **more flexibility**: put synthetic data in the cloud, make it available as Open Data (democratization), ...
- Synthetic data can supply **digital twins** or test environments with plenty of data, and facilitate prototyping.
- The field is fast evolving while also **steadily maturing**. Multiple vendors already offer qualitative solutions.

- **Inflated expectations**: a synthetic dataset still differs from the original, and is therefore not always useful for every usecase.
- Synthetic data should not be taken at face value. **User discretion** is advised when interpreting results based on a synthetic dataset.
- Qualitative synthesis **remains challenging** in some common cases:
 - For hierarchical or very complex data
 - For small datasets, datasets with many columns, or with many unique values
- Creating good synthetic data still **requires expertise**, domain knowledge, careful verification and validation, and a good grasp of statistics.

- Papers on diffusion models for tabular text are starting to appear:

TabDDPM: Modelling Tabular Data with Diffusion Models
